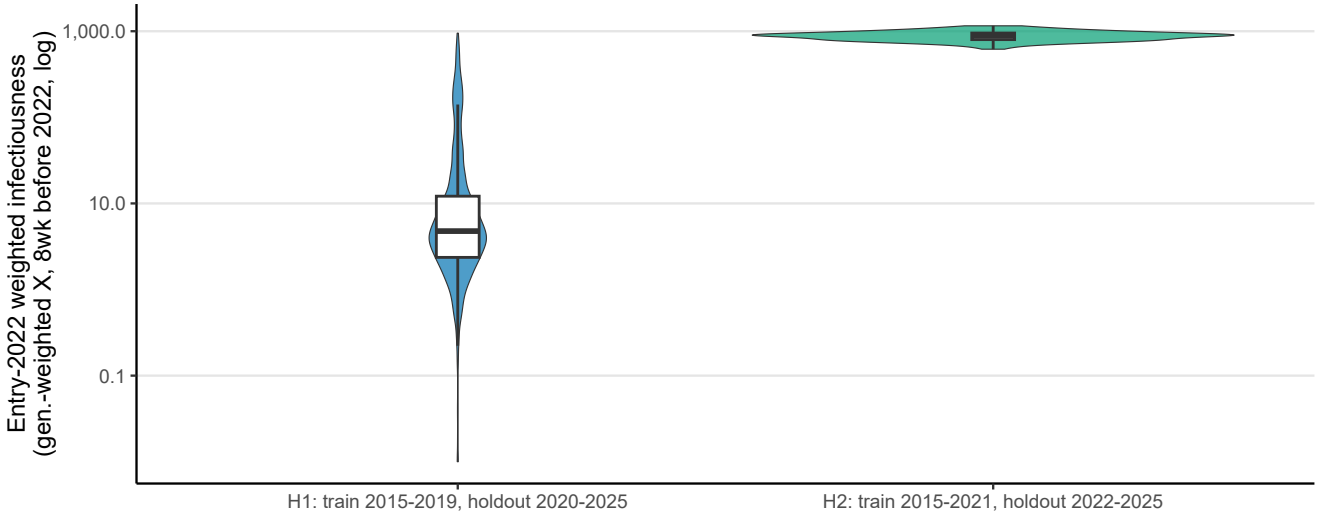

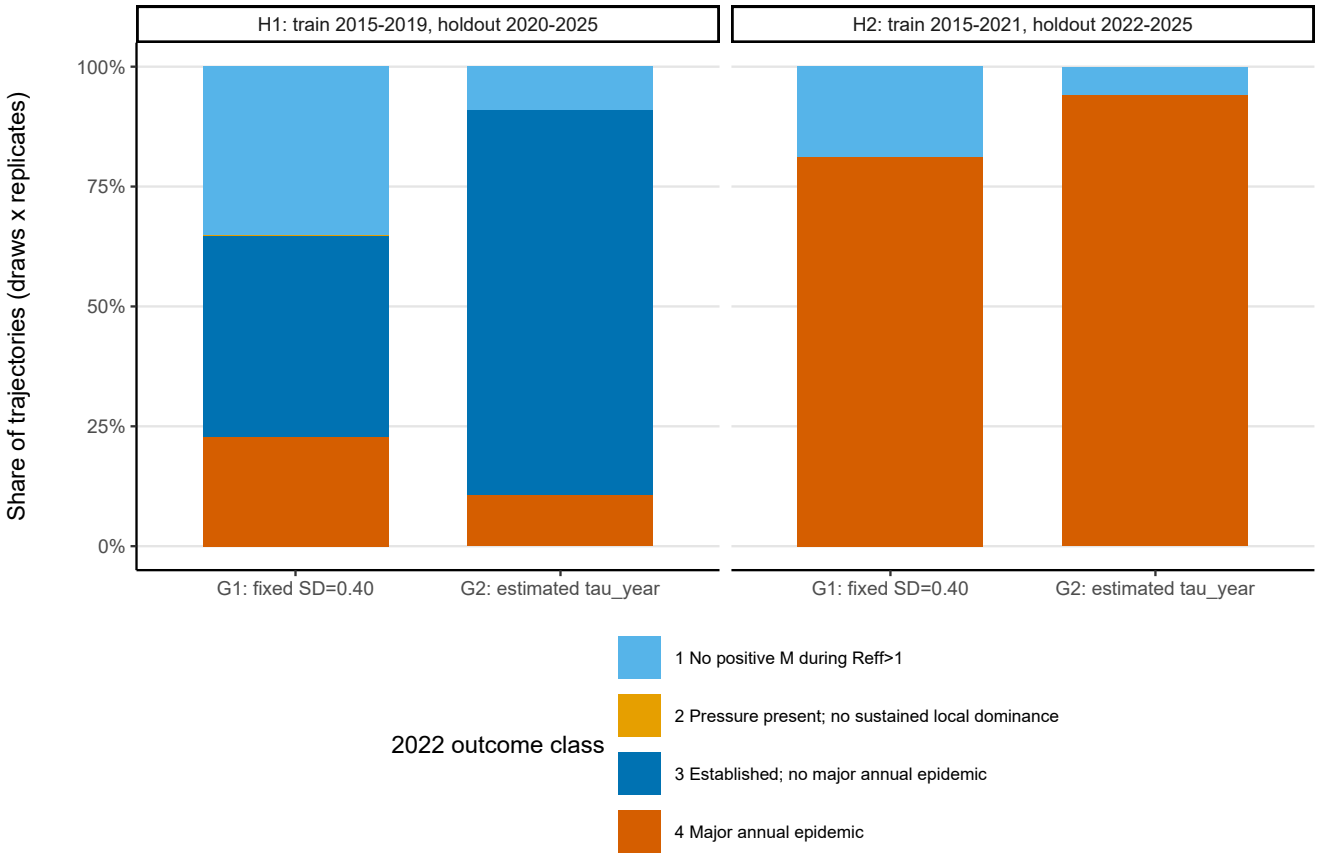

FIG22. Introduction and establishment diagnostics (2022)

A: H1's entry infectiousness comes from its OWN 2-year stochastic holdout simulation (2020-2021, no real data); H2's comes directly from the training-only posterior fitted to REAL observed 2015-2021 surveillance.

B: mechanism classification -- establishment (class 3+4) is common in H1/G2 (90.9%), but crossing the major-epidemic threshold (class 4) is rare (10.6%); in H2/G2 the two are nearly identical (94.0% vs 99.6%).

PROVISIONAL: H1/H2 have low but nonzero divergences and incomplete mixing; tau_year upper-tail reliability is not fully established. Training-derived quantities (posterior draws) are distinguished from stochastic holdout simulations (replicate-level trajectories) and from observed validation data (never used to fit/calibrate the holdout).
