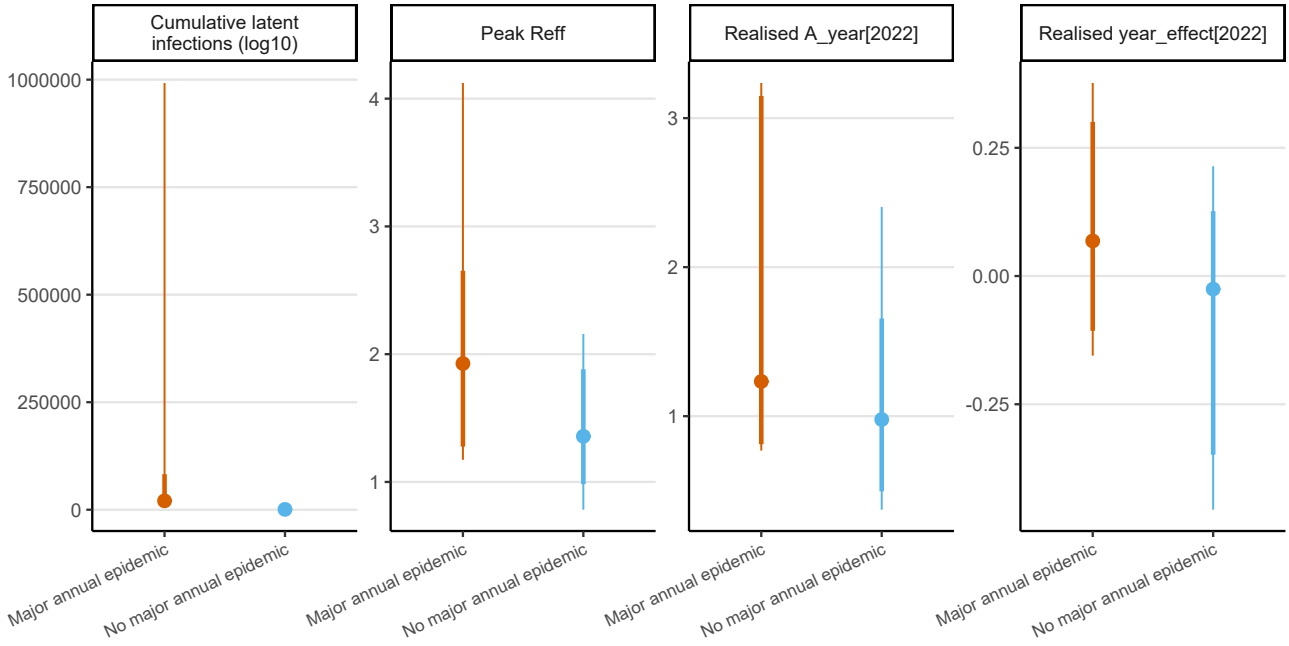

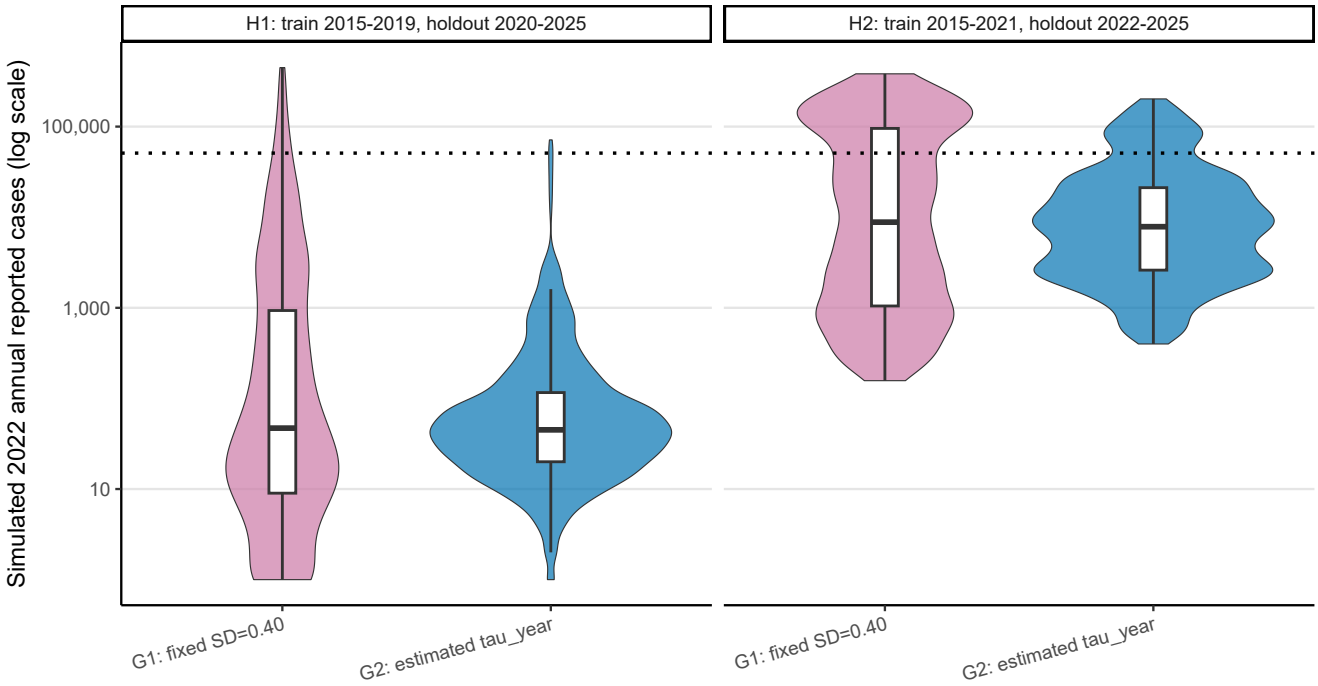

FIG23. Mechanistic explanation of the 2022 prediction failure (H1/G2)

A: H1/G2 trajectories split by 2022 outcome (descriptive; conditioning on simulated outcome, not a causal contrast). Point=median, thick bar=80% range, thin bar=95% range across draws x replicates.

B: simulated 2022 predictive distributions vs. the observed total (dotted line = 50,986 cases, never used to fit/calibrate).

PROVISIONAL: H1/H2 have low but nonzero divergences and incomplete mixing; tau_year upper-tail reliability is not fully established. Training-derived quantities (posterior draws) are distinguished from stochastic holdout simulations (replicate-level trajectories) and from observed validation data (never used to fit/calibrate the holdout).
